The AOS product reliability report summarizes the qualification results for AOZ5117QI-02 in QFN5x5-31L package. Accelerated environmental tests are performed on a specific sample size, samples are electrically tested before and after each stress time point. Review of final electrical test results confirm that AOZ5117QI-02 pass the AOS quality and reliability requirements. The released products will be categorized by its process family and routinely monitored for continuous improvement of product quality.

II. Reliability Evaluation

The presentation of FIT rate for the individual product reliability is restricted by the actual burn-in sample size of the product technology. Failure Rate Determination is based on JEDEC Standard JESD 85.

FIT rate (failures per billion device hours): 0.286

MTTF = 3,494.2 million hrs

Condition: $V_o = 18V$, $T_o = 55^\circ C$, $V_{s(DriverIC)} = 28V$, $V_{s(HS MOSFET)} = 30V$, $V_{s(LS MOSFET)} = 20V$ and $T_s = 150^\circ C$

Sample Size: MOSFET = 6,153, Driver IC = 8,669

The failure rate (λ) is calculated as follows:

$$\lambda = \chi^2[CL, (2f+2)] / 2 \times [1 / (SS \times t \times AF)]; \text{ [equation 1]} \quad \text{where} \quad \begin{array}{l} CL = \% \text{ of confidence level} \\ f = \text{number of failure} \\ SS = \text{sample size} \\ t = \text{stress time} \end{array}$$

Looking up the $\chi^2/2$ table for zero failure (burn-in) with 60% confidence, the value of $\chi^2[CL, (2f+2)] / 2$ is 0.92.

The Acceleration Factor (AF) is calculated from the following formula (both temperature and voltage acceleration factors are used in the final acceleration factor calculation):

$$AF = AF_T \times AF_V = \exp[(E_a/k) \times (1/T_o - 1/T_s)] \times \exp[\beta (V_s - V_o)] \quad \text{where} \quad \begin{array}{l} E_a = \text{activation energy} \\ k = \text{Boltzmann constant} \\ T_o = \text{operating } T_J \\ T_s = \text{stress } T_J \\ V_s = \text{stress voltage} \\ V_o = \text{operating voltage} \\ \beta = \text{voltage acceleration coefficient} \end{array}$$

Assuming typical operating environment, $V_o = 25V$, $T_o = 55^\circ C$, $E_a = 0.7eV$, $V_{s(DriverIC)} = 28V$, $V_{s(MOSFET)} = 30V$, $T_s = 150^\circ C$, $\beta = 0.5$ (silicon defect)

$$AF(DriverIC) = \exp \left[\left(\frac{0.7}{8.617E-5} \right) \cdot \left(\frac{1}{273+55} - \frac{1}{273+150} \right) \right] \cdot \exp[0.5 \cdot (28V - 18V)]$$

$$AF(HS MOSFET) = \exp \left[\left(\frac{0.7}{8.617E-5} \right) \cdot \left(\frac{1}{273+55} - \frac{1}{273+150} \right) \right] \cdot \exp[0.5 \cdot (30V - 18V)]$$

$$AF(LS MOSFET) = \exp \left[\left(\frac{0.7}{8.617E-5} \right) \cdot \left(\frac{1}{273+55} - \frac{1}{273+150} \right) \right] \cdot \exp[0.5 \cdot (20V - 18V)]$$

Substituting the values in equation 1, we have $\lambda = 2 \cdot \lambda(MOSFET) + \lambda(DriverIC) =$

$$0.92 \cdot \frac{2}{\text{Sample Size} \cdot \text{Stress Duration} \cdot AF(MOSFET)} + \frac{1}{\text{sample Size} \cdot \text{Stress Duration} \cdot AF(DriverIC)} \text{ hr}^{-1}$$

$\lambda = 0.286 \cdot 10^{-9} \text{ hr}^{-1}$ or 0.286 FIT; MTTF = $(1/\lambda) = 3,494.2$ million hrs = 398,877 years

The calculation shows failure rate is 0.286 FIT, MTTF is 3,494.2 million hours under typical operating conditions.
